

# **Quick Facts**

## **About...Pertussis (Whooping Cough)**

#### What is pertussis?

Pertussis, also called whooping cough, is a disease caused by bacteria. It may cause coughing fits that can cause breathing problems. Pertussis can lead to pneumonia (inflammation of lungs), seizures, and sometimes death. Most of these serious problems occur in infants who are less than a year old. Pertussis is often more mild in older children and adults. Indiana has several hundred reported cases of pertussis every year.

#### How is pertussis spread?

Pertussis is spread by contact with nose or throat droplets from an infected person. This can happen when an infected person coughs or sneezes. An infected person can spread the disease for up to three weeks from the time the cough begins. However, after five days of antibiotics, an infected person cannot spread pertussis.

#### Who is at risk for pertussis?

People who have not gotten a full series of pertussis vaccines or who have not received pertussis vaccine for several years are at a higher risk for pertussis. Infants who are too young to be fully vaccinated are at greatest risk for severe illness and death from pertussis.

## How do I know if I have pertussis?

If you have had close contact with someone who has been diagnosed with pertussis or if you have the symptoms described above, you should talk to your doctor. Your doctor may test you and prescribe antibiotics for treatment.

## What are the symptoms of pertussis?

The symptoms of pertussis occur in three stages:

- 1. During the first stage, symptoms are like a cold: slight fever, sneezing, runny nose, and dry cough.
- 2. During the second stage (about 1-2 weeks later), the cough becomes more intense. There may be short, intense coughing spells followed by a long gasp for air. The coughing fits may be followed by vomiting, nose bleeds, or bluish color to the lips or face.
- 3. During the third stage, the cough is less intense and less frequent. The cough stops, although this may take several months.

## **How is pertussis treated?**

While antibiotics make pertussis less contagious, they do not get rid of the cough unless taken very early in the illness. Everyone who lives in the same house of someone with pertussis should receive antibiotics to prevent spreading pertussis to others. Other people, such as playmates and classmates, might need antibiotics as well.

## How can pertussis be prevented?

Keep you and your children up to date with vaccines. The diphtheria, tetanus, pertussis (DTaP) vaccine is a five dose series for children under 7 years of age. It is given at the 2 month, 4 month, 6 month, and 12-15 month well baby visits and again before kindergarten at 4-6 years of age. Teens and adults (ages 10 years and older) should also get one dose of Tdap (tetanus, diphtheria, pertussis) vaccine to protect against pertussis. It is very important anyone having contact with an infant be fully vaccinated with the correct pertussis vaccine for their age. Tdap can be given no matter how much time has passed since the last dose of tetanus vaccine. Indiana requires that students in grades 6-12 get a single dose of Tdap.

See your doctor to decide if you need a vaccine against pertussis.
